The concept of unique normal form is formulated in terms of a spectral sequence. As an illustration of this technique some results of Baider and Churchill concerning the normal form of the anharmonic oscillator are reproduced. The aim of this paper is to show that spectral sequences give us a natural framework in which to formulate normal form theory.

1. INTRODUCTION

The goal of this paper is to show that spectral sequences give us a natural language in which to describe the process of computing the unique normal form. For a solid modern introduction to normal form theory and its historical development, see [Mur03b]. Although this is in no way intended as a review of (unique) normal form theory, let me give the reader some references to the literature which will at least help to create the impression that this is a subject that still gets a lot of attention nowadays: [YY01b, Yu01, YY01a, Yu99, BY98, BY99a, BY99b, Ush84a, Ush84b, WCW01, Che01b, Che01a, CDD99, CDD00a, CDD00b, Bry01, BW94, Bru89, Gae01b, CG99b, Gae01a, CG99a, Gae99a, Gae00, Gae99b, BCGM98].

Consider formal vectorfields at equilibrium and apply formal transformations to them, assuming for the moment that the linear part of the field is already in normal form (as in Jordan normal form). A unique normal form, as it is called in the literature, is by no means unique. But if two different procedures are used to compute the unique normal form, with result $N_1(v)$ and $N_2(v)$, say, then one should have $N_1(v) = N_1(N_2(v))$ and vice versa. If this is not the case, then surely at least one of the procedures does not yield a unique normal form. As observed by A. Baider, the uniqueness is more...
apparent in the space of allowable transformations. Once we know there are no transformations left to us, the result is the unique normal form.

The process of computing normal forms consists of solving the so-called homological equation. Much as this is supposed to remind one of homology, this is never in any way used. In this paper I will try and formulate normal form theory in terms of cohomology, using the framework of spectral sequences. The theory of spectral sequences is set up to do approximate calculations in filtered and graded differential modules, and therefore is a likely candidate for a theoretical tool. The technical problem is, that one would like to do all calculations with the approximate normal form, since it is very important whether certain coefficients in this normal form are invertible or not. This has as a consequence that we do not have one differential operator, but many. However, they converge in the filtration topology and we can easily adapt the usual construction to suit our problem.

Having seen the theoretical part, the reader may still have absolutely no idea what it means, so I have given as an illustration in section 5 one of the few systems where the unique normal form can be completely understood, namely the anharmonic oscillator, following the analysis in [BC88, Bai89]. For other examples, see [BS91, SvdM92]. In fact, the results as presented here are slightly more general than Baider and Churchill’s, since we allow coefficients in a local ring instead of a field. To say that they are new would, however, be an overstatement. The analysis does however provide us with a nice illustration of the spectral sequence method. All proofs are reduced to elementary calculations, and all the filtering arguments that complicate Baider’s proof are already contained in the setup. It is tempting to do same same for another class of equations, namely those planar vectorfields with nilpotent linear part, but one look at the length of the resulting analysis in [BS92] is convincing enough not to present this as an example, since it would be another big paper, and no new results in it! However, it is also clear that the basic construct in loc.cit. is the Tic-Tac-Toe–construction, cf. section 5.2.1, and the whole spectral sequence approach seems completely natural. Since the whole analysis in this case relies on the judicious choice of a second filtering, one probably needs to set up a context with two filtrations, and for each of these one constructs a coboundary operator on a bicomplex $E_{q_1,q_2}^{p_1,p_2}$. The reader is encouraged to reformulate a familiar problem in the language of spectral sequences, just to experience whether this approach is as natural as claimed.

A similar approach has been used in [Arn76, Arn75],[AGZV85, Chapter 14] in the context of singularity theory. Undoubtedly, from a higher point of view, one can view the present paper as a simple corollary of the previous work by Arnol’d et.al.. Yet it took the author quite some time to figure this out. So here we have an idea that has been around for a quarter of
a century and it has not been picked up by the normal form community, despite the fact that in the meantime serious work was done to formulate the theoretical basis in terms of filtered Lie algebras. That means that now it is time to make some propaganda for the method and illustrate its power.\footnote{Added in proof: The reader may also want to consult \cite{Chu02} and \cite{Mur03a}.}

**Acknowledgment** The author would like to thank Jim Murdock for long e-mail discussions and valuable questions and comments, and André Vanderbauwhede for listening to his explanations on their beach walks at Cala Gonone. Thanks go to the Newton Institute and the organizers of the Integrable Systems program and the Netherlands Organization for Scientific Research (NWO) for their financial support.

**2. NORMAL FORMS, FIRST STEPS**

In the theory of normal forms of ordinary differential equations at equilibrium, one studies equations of the form

\[
\dot{x} = v_0 + v_1 + \cdots,
\]

where \(v_i\) stands for the Taylor expansion of the vectorfield of degree \(i + 1\).

One computes a normal form by applying the formal transformation

\[
x = y + X_1 + X_2 + \cdots,
\]

and this leads to the so-called homological equation

\[
[v_0, X_1] = v_1 - v_1^0,
\]

where \(v_1^0\) is the first order normal form at the quadratic level. Why this is called a homological equation is seldom explained and this paper is written to provide an explanation of this terminology and to define the so-called unique normal form in terms of spectral sequences.

Let us start by constructing a short complex as follows. \(V\) is the space spanned by the given vector field \(v = v_0 + v_1 + \cdots\), and let \(W\) be the space of vectorfields starting with linear terms. Consider now the standard homology complex (where \(W\) is seen as the representation space of the Lie algebra \(V\))

\[
\begin{align*}
0 & \leftarrow W \leftarrow V \otimes W \leftarrow \bigwedge^2 V \otimes W \cdots \\
\end{align*}
\]

Since \(\dim V = 1\), \(\bigwedge^2 V = 0\), and one has the short sequence

\[
0 \leftarrow W \leftarrow V \otimes W \leftarrow 0,
\]
where the only nonzero boundary map $\partial$ is given by

$$\partial(v \otimes w) = [v, w].$$

Normal form theory of vectorfields is complicated by the fact that the vectorfield with which we act is being changed at the same time. Therefore we define a sequence of vectorfields $v^{j+1} = exp(ad(t^j))v^j$, with $v^0 = v$ and one-dimensional spaces $V^j = \langle v^j \rangle$, $v^j \in W$. The corresponding differentials can be composed as usual, since one of the two will always be zero anyway.

### 3. SPECTRAL SEQUENCE

"Spectral sequences were invented by Jean Leray, as a prisoner of war during World War II, in order to compute the homology (or cohomology) of a chain complex. They were made algebraic by Koszul in 1945." [Wei94].

We now formulate the general theory in terms of filtered Lie algebras, and illustrate it by making comments on the interpretation in terms of vectorfields. The whole construction will work equally well for Hamiltonian systems, to mention one important class of examples for normal form theory.

Suppose that $W$ is a filtered Lie algebra $W = W_0 \supset W_1 \supset W_2 \supset \cdots$, with $\bigcap_{i=0}^{\infty} W_i = 0$ and $[W_i, W_j] \subset W_{i+j}$. Consider the short complex

$$0 \leftarrow W \xrightarrow{\partial} V^q \otimes W \leftarrow 0,$$

with $V^q = \langle v^q \rangle$, $v^0 = v$ and the higher $v^q$ will be defined in the next section. We assume here that $v^{q+1} = v^q \pmod{W_{q+1}}$. This corresponds to the fact that one does not perturb lower order terms in the process of normalizing the vectorfield. The filtration of $W$ induces a filtration on $\bigwedge^n V^q \otimes W$ and we denote the filtration on the chain complex by

$$F^q = F^q_0 \supset \cdots \supset F^q_p \supset \cdots, \quad \text{with} \quad F^q_i = \sum_{n=0}^{1} \bigwedge^n V^q \otimes W_i.$$

For the normal form theory, we are not so much interested in the $V^q$ part of these spaces, so instead we work with

$$K = K_0 \supset \cdots \supset K_p \supset \cdots, \quad \text{with} \quad K_i = W_i \oplus W_i =: \mathcal{N}_i^0 \oplus \mathcal{T}_i^0.$$

In many problems one can think of $\mathcal{N}$ and $\mathcal{T}$ as essentially the same space, but if one considers for instance problems with time-reversal symmetry,
then one should take for $T$ the elements that are invariant under the group action, and for $N$ those that change sign (which is then compensated for by simultaneous time-reversal).

We write $\partial_q(x, y) = ([v^q, y], 0)$, $x \in N^0$; $y \in T^0_i$. One should think of $N^0$ as the space where the normal form of the vectorfield lives, and $T^0_i$ is the space of transformations.

The reader may at this point wonder whether the fact that the boundary relations are trivially satisfied will also trivialize the subsequent application of the theory. The interesting thing is that it does not. The interaction of the cohomology with the filtering is sufficiently complicated to confuse anyone without a good organization. It is the claim of this paper that spectral sequences provide this organization.

The following is an almost standard introduction, taken from [God58], to spectral sequences, which is reproduced here for the convenience of the reader. For more information on spectral sequences, see [McC99, McC01]. The main difference with the usual approach is that we allow the $\partial$ to vary (by changing $V^p$). The assumption that $v^j$ converges in the filtration topology ensures that this does not damage the usual constructions.

We now consider an abstract homology complexes

$$0 \leftarrow K_p \xrightarrow{\partial} K_p \leftarrow 0,$$

with $r = -1, 0, 1, \cdots$ and $\partial_{-1} = 0$. Now let $Z^r_p$ be the set of all $x \in K_p$ such that $\partial_r x \in K_p$. We assume the following property in some of our lemmas.

**Property 3.1.** If $x \in Z^r_p$ or $x \in Z^{-1}_{p+1}$, then $\partial_r x - \partial_{r-1} x \in Z^{-1}_{p+r}$. This property follows in the case of normal form theory from the fact that the sequence of normal forms converges in the filtration topology, that is to say, higher order calculations do not change lower order ones.

**Lemma 3.1.** The complex defined above, with $\partial_q(x, y) = ([v^q, y], 0)$, $x \in N^0_i, y \in T^0_i$, has Property 3.1.

*Proof.* Since $v^r = v^{r-1} + w_r$, with $w_r \in K_r$, $\partial_r x = \partial_{r-1} x + ([w_r, x], 0)$ and $([w_r, x], 0) \in Z^{-1}_{p+r}$. 

**Lemma 3.2.** Let $(K_p, \partial_r)_{p=0, r=-1}$ be homology complexes with Property 3.1. Then $Z^{r-1}_{p+1} \subset Z^r_p$.

*Proof.* If $x \in Z^{r-1}_{p+1}$ then $x \in K_{p+1} \subset K_p$ and $\partial_r x \in K_{p+r}$. By Property 3.1, $\partial_r x \in K_{p+r}$. 

Lemma 3.3. Let \( \{K_p, \partial_r\}_{p=0,r=-1}^\infty \) be homology complexes with Property 3.1. Then \( \partial_{r-1}Z_{p-r+1}^{r-1} \subseteq Z_p^r \).

Proof. If \( x \in \partial_{r-1}Z_{p-r+1}^{r-1} \) then \( x = \partial_{r-1}y \) with \( y \in Z_{p-r+1}^{r-1} \), implying that \( y \in K_{p-r+1} \) and \( \partial_{r-1}y \in K_p \). It follows that \( x \in K_p \) and \( \partial_r x = 0 \).

Definition 3.1. Let \( \{K_p, \partial_r\}_{p=0,r=-1}^\infty \) be homology complexes with Property 3.1. Then for \( r \geq 0 \),

\[
E_r^p = Z_p^r/(\partial_{r-1}Z_{p-r+1}^{r-1} + Z_{p+1}^{r-1}), \quad E_r^p = \sum_p E_r^p.
\]  

I would like to think as this as the natural definition of what the computation of normal forms is all about. One divides out whatever can be transformed away, the \( \partial_{r-1}Z_{p-r+1}^{r-1} \) term and the transformations that trivially give rise to higher order terms, the \( Z_{p+1}^{r-1} \) term. The \( Z_p^r \) itself sees to it that only those transformations are left that do not perturb the previously computed lower order terms in normal form. The next theorem then identifies these natural spaces in which the normal form and the allowable transformations live into cohomology spaces. This identification greatly simplifies the calculation procedure and allows us to use the familiar tools used in the analysis of bicomplexes.

Theorem 3.1. Let \( \{K_p, \partial_r\}_{p=0,r=-1}^\infty \) be homology complexes with Property 3.1. Then there exists on the graded module \( E' \) a differential \( d' \) such that \( H(E') \) is canonically isomorphic to \( E_{r+1}^r \), \( r \geq 0 \).

Proof. Here only the definition of \( d' \) is given. For the full proof, see Appendix 1. The differential \( \partial_r \) maps \( Z_p^r \) into \( Z_{p+r}^r \) and \( \partial_{r-1}Z_{p-r+1}^{r-1} + Z_{p+1}^{r-1} \) into \( \partial_r Z_{p+1}^{r-1} \). Let \( x \in \partial_r Z_{p+1}^{r-1} \). Then there is a \( y \in Z_{p+1}^{r-1} \) such that \( x = \partial_r y \in \partial_{r-1}Z_{p-r+1}^{r-1} + Z_{p+1}^{r-1} \), using Property 3.1. Since

\[
E_{p+r}^r = Z_{p+r}^r/(\partial_{r-1}Z_{p+1}^{r-1} + Z_{p+1+r}^{r-1}),
\]

one sees that \( \partial_r \) induces a map \( d'_r : E_p^r \rightarrow E_{p+r}^r \).

4. NORMAL FORM THEORY

The direct sum decomposition \( K_p = N_p^r \oplus T_p^r \) induces a analogous decomposition \( E_p^r = N_p^r \oplus T_p^r \). We will see from the normal form calculations that this decomposition codifies the form of the normal terms at level \( r \) and
degree \( p + 1 \) in \( \mathcal{N}_p^r \) and the terms we can still use in the transformation in \( T_p \). Let us see whether this whole construction makes some sense in terms of classical normal form theory. Take \( \nu^0 = \nu \), the vectorfield we start with.

We construct \( E_{p+1}^1 \). By definition

\[
E_{p+1}^1 = Z_{p+1}^1/(\partial_h Z_p^0 + Z_p^0_{p+1}).
\]

We know that \( Z_p^1 = \{ x \in K_p | \partial_h x \in K_{p+1} \} \). We write for each \( x \in Z_p^1 \), \( x = (n, t) \), with \( t \) such that \([v^0, t] \in W_{p+1} \). Dividing by \( \partial_h Z_p^0 \) means we put \( n \) in first order normal form, that is, \( n \in \mathcal{N}_p^1 \), since \( \partial_h Z_p^0 \) is exactly the image of \( \text{ad}(v^0) \) restricted to the \( p + 1 \)-degree terms both in the source and the object space. Thus \( E_{p+1}^1 \) can be identified with pairs \((n, t)\), with \( n \) in first order normal form (with respect to the linear part of the vector field \( v^0 \)) and \( t \in T_p^1 \) such that it does not change the \( p + 1 \)-degree terms when we use it to transform the equation. This means that the lowest order term in \( t \) commutes with the linear term of the vectorfield.

In the following we use the subindex to indicate the graded part induced by the filtration, as in \( v_p \in W_p/W_{p+1} =: G_p \). In the context of formal power series vectorfields these are just the homogeneous parts of degree \( p + 1 \).

We now write \( v_p^1 = v_p^1 + [v_p^0, t_p^0] \), with \([v_p^1, 0] \in E_p^1 \) (where the \([.]\) denote equivalence classes, not Lie brackets!) and \([0, t_p^0] \in E_p^0 \). The decomposition of \( G_1 \) implicit in the equality amounts to the identification \( G_1 \approx (G_1/\ker(\text{ad}(v_0^0)G_1)) \oplus \ker(\text{ad}(v_0^0)G_1) \), which in turn is equivalent to the choice of a complement for \( \ker(\text{ad}(v_0^0)) \) in \( G_1 \). Choosing such a complement is standard in normal form theory (which is not to say there is a standard choice!) and we now see a homological formulation. We define

\[
\nu^1 = \exp(\text{ad}(t_1^0))\nu^0.
\]

We see that

\[
\nu^1 = v^0 + v^1 + \text{ad}(t^0_1)v^0 \quad (\text{mod } W_2)
\]
\[
= v^0 + v^1 + [v^0, t^1_1] + [t^1_1, v^0] \quad (\text{mod } W_2)
\]
\[
= v^0 + v^1 \quad (\text{mod } W_2).
\]

We are now ready to go to round two. We write \( v_2^1 = v_2^1 + [v_0^0, t_2^0] + [v_0^0 + v_1^0, t_1^1] \), with \( v_2^1 \in \mathcal{N}_2^2 \), \( t_2^0 \in T_2^0 = W_2 \) and \( t_1^1 \in T_1^1 \), with \( E_2^2 = \mathcal{N}_2^2 \oplus T_2^2 \). Let us now compute \( d_{p+1}^1(v_p^1, t_p^1) = (\pi_p^{p+1}[v_p^1, t_p^1], 0) \), where \( \pi_p^{p+1} \) is the projection on \( \mathcal{N}_{p+1}^r \) and \( d_p^{p+1} \) is defined in the proof of Theorem 3.1. So this gives us the contribution of the transformation to the normal form of the terms of one degree higher, and we see that the general spectral sequence approach gives us exactly those terms that we have always been computing. This means that this is the natural language in which to formulate the theory.
Then we define
\[ v^2 = \exp(ad(t_1^1 + t_2^0))v^1. \]
In general we write
\[
(v_{j+1}^j, 0) = (v_{j+1}^{j+1}, 0) + \sum_k \partial_k(0, t_{j+1-k}^k) (\mod K_{j+2})
\]
and transform with
\[ v^{j+1} = \exp(ad(\sum_k t_{j+1-k}^k))v^j. \]

Here one has \([v_{j+1}^{j+1}, 0]) \in Z_{j+1}^{j+1}, \) and \([\partial_j(0, \sum_k t_{j+1-k}^k)] \in \partial_j Z_1^j + Z_{j+2}^j. \) Thus one can view \((v_{j+1}^{j+1}, 0)\) as an element in \(E_{j+1}^{j+1}.\)

One sees that the definitions of the spaces allow one to find all these elements in principle, but one has to be aware of possible problems if the transformation space is not locally finite, that is the factor spaces are not finite dimensional. This is for instance the case if one considers equations of the type
\[ \dot{x} = \epsilon f(t, x). \]
If \(f\) is periodic in \(t\), one can use averaging to solve the homological equation [San94]. The filtering is given here by the powers of \(\epsilon\). If they are finite dimensional, everything is just linear algebra. Most of normal form theory is about doing the linear algebra in an effective way by using the spectral information of the linear part of the vectorfield, but this only works well for the first order normal form, since the Lie algebra involved in the higher order normal form is not reductive (Try to imbed an element in \(W_1\) in an \(sl(2, \mathbb{R})\)). This is treated in [San94].

Continuing in this fashion, we decrease the normal form space and the space of transformations we can use, until in the end we have the unique normal form space, and the transformations that are left commute with the normal form of \(v\), that is, they are conjugate to symmetries of \(v\).

**Theorem 4.1.** Suppose \(E^\infty\) exists and let \(v^\infty\) be the final normal form of \(v\). Then we can identify \(v^\infty_p\) with an element in \(E^\infty_p = E^\infty_p\) of the form
Furthermore we can identify any symmetry $s$ of $v$ with a symmetry $s^\infty$ of $v^\infty$ and $(0, s^\infty_p) \in E^\infty_p$.

5. THE ANHARMONIC OSCILLATOR

"[. . .] the most powerful method of computing homology groups uses spectral sequences. When I was a graduate student, I always wanted to say, nonchalantly, that such and such is true "by the usual spectral sequence argument," but I never had the nerve" [Rot96].

Let us, just to get used to the notation, treat the simplest normal form problem we can think of, the anharmonic oscillator. The results we obtain were obtained first in [BC88, Bai89].

We will take our coefficients from a local ring $R$ containing $\mathbb{Q}$. Then the noninvertible elements are in the maximal ideal, say $m$, and although subsequent computations are going to affect terms that we already consider as fixed in the normal form calculation, they will not affect their equivalence class in the residue field $R/m$. So the convergence of the spectral sequence is with respect to the residue field. The actual normal form will contain formal power series which converge in the $m$-adic topology. In [Bai89] it is assumed there is no maximal ideal, and $R = \mathbb{R}$. When in the sequel we say that something is in the kernel of a coboundary operator, this means that the result has its coefficients in $m$. When we compute the image then this is done first in the residue field to check invertibility, and then extended to the whole of $R$. This gives us more accurate information than simply listing the normal form with coefficients in a field, since it allows for terms which have nonzero coefficients, through which we do not want to divide, either because they are very small or because they contain a deformation parameter in such a way that the coefficient is zero for one or more values of this parameter.

Definition 5.1. We define the Hilbert-Poincaré series of $E^r$ as

$$P[E^r](t) = \sum_{p=0}^{\infty} \left( \dim N^r_p - \dim T^r_p \right) t^p.$$

If it exists, we call $I(E^r) = P[E^r](1)$ the index of the spectral sequence at $r$. In the anharmonic oscillator problem, $P[E^0](t) = 0$. Let, with

\footnotetext[2]{One can think for instance of formal power series in a deformation parameter $\lambda$, which is the typical situation in bifurcation problems. Then a term $\lambda x^2 \frac{\partial}{\partial x}$ has coefficient $\lambda$ which is neither zero nor invertible, since $\frac{1}{\lambda}$ is not a formal power series.}
\( k \geq -1, l \geq 0, q \in \mathbb{Z}/4, A^k_{k+l} = \frac{i^q}{\pi} x^{k+1} y^l + i^{2q} x^{k+1} \frac{\partial}{\partial y} \). Since \( A^l_{k+q+2} = -A^l_{k} \), a basis is given by \( \langle A^l_{k} \rangle_{k=-1, \ldots, l=0, \ldots, q=0,1} \), but we have to compute in \( \mathbb{Z}/4 \). The commutation relation is

\[
[A^k_{k+l}, A^m_{m+n} \rangle = (m-k)A^k_{k+m+l+n} + nA^m_{m+n} - (k-l)q = lA^l_{k+m+l+n+n}.
\]

Then the anharmonic oscillator is of the form

\[
v = A^{0,1}_0 + \sum_{q=0}^{\infty} \alpha^{k-l,q}_k A^{k-l,q}_{k+l}, \alpha_k \in R.
\]

Since

\[
[A^{0,1}_0, A^{k-l,q}_{k+l}] = (k-l)A^{k-l,q}_{k+l+1}
\]

we see that the kernel of \( ad(A^{0,1}_0) \) consists of those \( A^{k-l,q}_{k+l} \) with \( k = l \) and the image of those with \( k \neq l \). We are now in a position to compute \( E^1_p \). We have by definition that \( Z^1_p = K_p = W_p \oplus W_p \). Then

\[
Z^1_p = \{ x \in K_p | \partial x \in K_{p+1} \} = \{ (x, y) \in K_p | [v^0_0, y] = 0 \} = W_p \oplus \ker ad(v^0_0)|_{W_p}.
\]

Thus,

\[
E^1_p = Z^1_p / (\partial Z^0_p + Z^0_{p+1}) = \ker ad(v^0_0)|_{G_p} \oplus \ker ad(v^0_0)|_{G_p},
\]

since \( W_p = im ad(v^0_0)|_{W_p} \oplus \ker ad(v^0_0)|_{W_p} \) and \( G_p = im ad(v^0_0)|_{G_p} \oplus \ker ad(v^0_0)|_{G_p} \), due to the semisimplicity of \( A^{0,1}_0 \). It follows that \( P[E^1](t) = 0 \). In general we have

\[
\mathcal{T}^1_{2p} = \mathcal{N}^1_{2p} = (A^{0,0}_{2p}, A^{0,1}_{2p})_R \]

and \( \mathcal{T}^1_{2p+1} = \mathcal{N}^1_{2p+1} = 0 \). One has the following commutation relations

\[
[A^{0,p}_{2k}, A^{0,q}_{2m}] = (m-k)A^{0,p+q}_{2k+2m} + mA^{0,q-p}_{2k+2m} - kA^{0,p-q}_{2k+2m}.
\]

For later use we write out the three different cases:

\[
[A^{0,0}_{2k}, A^{0,0}_{2m}] = 2(m-k)A^{0,0}_{2k+2m},
\]

\[
[A^{0,0}_{2k}, A^{0,1}_{2m}] = 2mA^{0,1}_{2k+2m},
\]

\[
[A^{0,1}_{2k}, A^{0,1}_{2m}] = 0.
\]
It follows that \( \mathcal{A} = \langle A_{2p}^{0,1} \rangle_{m \in \mathbb{N}} \oplus \langle A_{2p}^{0,1} \rangle_{m \in \mathbb{N}} \) is an abelian Lie algebra ideal in \( E^1 \), which itself is a \( \mathbb{N} \times \mathbb{Z}/2 \)-graded Lie algebra. We can consider \( E^1 \) as a central extension of \( E^1 \) with \( E^1 \).

We now continue our normal form calculations until we hit a term \( \nu_{2^r} = \beta_{2^r} \cdot A_{2^r}^{0,1} + \beta_{2^r} \cdot A_{2^r}^{1,0} \) with either \( \beta_{2^r} \) or \( \beta_{2^r} \) invertible. We have \( E^{2r} = E^1 \). We see that \( d_{2^r}^{2^r} \) is now nonzero, at least it is not zero by the previous argument, since it maps the even spaces on themselves. A general element in \( T_{2^r}^{2^r} \) is given by

\[
\nu_{2^r} = \sum_{q=0}^{1} \gamma_{2^r}^q A_{2^r}^{0,q}.
\]

We have, with \( p > r \),

\[
d_{2^r}^{2^r}(0, \nu_{2^r}) = (\beta_{2^r} \cdot A_{2^r}^{0,0} + \beta_{2^r} \cdot A_{2^r}^{1,0}) + (\beta_{2^r} \cdot A_{2^r}^{0,1} + \beta_{2^r} \cdot A_{2^r}^{1,0}) = (2(p-r)\beta_{2^r} \cdot A_{2^r}^{0,0} + 2p\beta_{2^r} \cdot A_{2^r}^{1,0} - 2r\beta_{2^r} \cdot A_{2^r}^{1,0}).
\]

We view this as a map from the coefficients at \( G_{2p} \) to those at \( G_{2r+2p} \) with matrix representation

\[
\begin{pmatrix}
2(p-r)\beta_{2^r} & 0 \\
-2r\beta_{2^r} & 2p\beta_{2^r}
\end{pmatrix}
\begin{pmatrix}
\gamma_{2p}^0 \\
\gamma_{2p}^1
\end{pmatrix}
\]

and we see that for \( 0 < p \neq r \) the map is surjective if \( \beta_{2^r} \) is invertible; if it is not, it has a one-dimensional image since we assume that in this case \( \beta_{2^r} \) is invertible.

### 5.1. Case \( \mathcal{A}^r; \beta_{2^r}^0 \) is invertible.

In this subsection we assume that \( \beta_{2^r}^0 \) is invertible. The following analysis is equivalent to the one in [Bai89, Theorem 4.11], case (3), \( j = r \), if \( \beta_{2^r}^1 = 0 \). For \( \beta_{2^r}^1 \neq 0 \), see section 5.2.

We have already shown that \( \text{im} \ d_{2^r}^{2^r} = \langle A_{2^r}^{0,1} \rangle_{2^r} \oplus 0 \) for \( p < r \) and \( \text{im} \ d_{2^r}^{2^r} = \langle A_{2^r}^{0,1} \rangle_{2^r} \oplus 0 \) for \( p = r \). Furthermore \( \ker \ d_{2^r}^{2^r} = G_2 \oplus \langle v_{2^r} \rangle \) and \( \ker \ d_{2^r}^{2^r} = G_2 \oplus \langle 0 \rangle \) for \( 0 < p < r \). We are now in a position to compute \( E_{2^r+1}^{2^r} = H^{2^r}(E^{2^r}) \). First of all, \( E_{2^r+1}^{2^r} = H^{2^r}(E^{2^r}) = \ker \ d_{2^r}^{2^r} / \text{im} \ d_{2^r}^{2^r} = \langle (A_{2^r}^{0,0}, A_{2^r}^{0,1}) \rangle \oplus 0 \). Then for \( p > r \) we find \( E_{2^r+1}^{2^r} = H^{2^r}(E^{2^r}) = \ker \ d_{2^r}^{2^r} / \text{im} \ d_{2^r-2^r}^{2^r} = \langle (A_{2^r}^{0,0}, A_{2^r}^{0,1}) \rangle \oplus 0 \) for \( 0 < p < r \) we find \( E_{2^r+1}^{2^r} = H^{2^r}(E^{2^r}) = \ker \ d_{2^r}^{2^r} = \langle (A_{2^r}^{0,0}, A_{2^r}^{0,1}) \rangle \oplus 0 \).
0). Obviously, $E^{2r+1}_{2p+1} = 0$. One has

$$E^\infty_{2p} = E^{2r+1}_{2p} = \begin{cases} A_{2p}^{0,0} A_{2p}^{0,1} \oplus A_{2p}^{0,0} A_{2p}^{0,1} p \\ m \ R \setminus m \ R \ R \ 0 \\
m \ m \ 0 \ 0 \ 1, \ldots, r - 1 \\
R \setminus m \ R \ R \ 0 \ r \\
0 \ 0 \ 0 \ 0 \ r + 1, \ldots, 2r - 1 \\
R \ 0 \ 0 \ 0 \ 2r \\
0 \ 0 \ 0 \ 0 \ 2r + 1, \ldots. \end{cases}$$

We see that

$$P^r[E^\infty](t) = \sum_{i=1}^{r-1} 2t^{2i} + t^{2r} + t^{4r}$$

and $I(E^\infty) = 2r$. The codimension of the sequence, which we obtain by looking at the dimension of the space with coefficients in $m$, is $2r - 1$. We can reconstruct the normal form out of this result. Here $c_{2p} \in m$ at position $A_{2p}^{0,0}$ means that the coefficient of $A_{2p}^{0,0}$ in $c_{2p}$ cannot be invertible. And $c_{2p} \in R \setminus m$ means that it should be invertible. While $c_{2p} \in R$ indicates that the coefficient could be anything in $R$. By ignoring the $mA_{2p}^{0,0}$ terms we obtain the results in [Bai89]. The $R \setminus m$-terms indicate the organizing center of the corresponding bifurcation problem.

Since we have no more effective transformations at our disposal, all cohomology after this will be trivial and we have reached the end of our spectral sequence calculation.

5.2. Case $A_r$: $\beta_{2r}^0$ is not invertible, but $\beta_{2r}^1$ is

The following analysis is equivalent to the one in [Bai89, Theorem 4.11], case (4), $k = r, l = q$. Since

$$d_{2p}^{2r}(0, t_{2p}) = 2(p - r)\beta_{2r}^0 \gamma_{2p}^0 A_{2p+2r}^{0,0} + 2p\beta_{2r}^0 \gamma_{2p}^1 A_{2p+2r}^{0,1} - 2r\beta_{2r}^1 \gamma_{2p}^0 A_{2p+2r}^{0,1}$$

we can remove all terms $A_{2p+2r}^{0,1}$ for $p > 0$ by taking $\gamma_{2p}^1 = 0$. This only contributes terms in $mA_{2p+2r}^{0,0}$. We obtain

$$E^{2r+1}_{2p} = \begin{cases} A_{2p}^{0,0} A_{2p}^{0,1} \oplus A_{2p}^{0,0} A_{2p}^{0,1} p \\ m \ R \setminus m \ R \ R \ 0 \\
m \ m \ 0 \ 0 \ 1, \ldots, r - 1 \\
m \ R \setminus m \ 0 \ R \ r \\
R \ 0 \ 0 \ 0 \ R \ r + 1, \ldots. \end{cases}$$
We see that

\[ P_r[E^{2r+1}](t) = \sum_{i=1}^{r} t^{2i} \]

and \( I(E^{2r+1}) = r \). The codimension is 2r.

5.2.1. Case \( A_2^q \): \( \beta_{2q}^0 \) is invertible

We now continue our normal form calculation until at some point we hit on a term

\[ \beta_{2q}^0 A_{2q}^{1,0} \]

with \( \beta_{2q}^0 \) invertible. The following argument is basically the Tic-Tac-Toe Lemma [BT82, Proposition 12.1] and this was a strong motivation to consider spectral sequences as a framework for normal form theory. The idea is to add the \( \mathbb{Z}/2 \)-grading to our considerations. We view \( \text{ad}(A_{0,1}^{2q} + \beta_{2q}^1 A_{2q}^{0,1}) \) as one coboundary operator \( d^{2r,1} \) and \( \text{ad}(\beta_{2q}^0 A_{2q}^{0,0}) \) as another, \( d^{2q,0} \). Both operators act completely homogeneous with respect to the gradings induced by the filtering and allow us to consider the bicomplex spanned by \( E^{3,0} \) and \( E^{1,1} \), where \( E^{3,0} = \langle A_{2q}^{0,0} \rangle \oplus \langle A_{2q}^{0,0} \rangle \) and \( E^{1,1} = \langle A_{2q}^{0,1} \rangle \oplus \langle A_{2q}^{0,1} \rangle \). Since \( \langle A_{2q}^{0,0} \rangle \), \( A_{2q}^{0,0} \), \( 2(p-q)A_{2q}^{0,0} \), \( A_{2q}^{0,0} \) and \( A_{2q}^{0,1} \), \( A_{2q}^{0,1} \) we see that the only nontrivial \( d^{2q,0} \)-cohomology is \( H_{d^{2q,0}}^0(E^{1,1}) \) or \( H_{d^{2q,0}}^0(E^{1,1}) \).

To compute the image of \( d^{2r,1} + d^{2q,0} \) we start with the \( E^{2r+1} \)-term. Take \( t_s^{(1)} = A_{2q}^{0,1} \). Then \( d^{2q,0} A_{2q}^{0,0} \in E_{2q+2s,1}^{2r+1} \), that is, we can write \( d^{2q,0} A_{2q}^{0,1} = d^{2r,1} d^{2q,0} t_s^{(2)} \), \( (s_1^{(2)} + t_s^{(2)}) = d^{2q,0} t_s^{(1)} + s_1^{(2)} \), \( s_1^{(2)} = s_1^{(2)} + t_s^{(2)} \), \( (d^{2r,1} + d^{2q,0})(t_s^{(1)} + t_s^{(2)}) = d^{2q,0} t_s^{(1)} + s_1^{(2)} \).

Looking at the \( d^{2q,0} \)-cohomology we see that this gives us a nonzero result under the condition \( 0 < s \neq r \).

The image of \( d^{2q} = d^{2r,1} + d^{2q,0} \) in \( E^{1,1} \) is spanned by

\[ \prod_{j=1}^{\infty} (A_{4q-2r+2j}^{0,1}) \oplus 0 \]

and in \( E^{1,1} \) by \( \prod_{j=1}^{\infty} (A_{2r+1}^{0,1}) \oplus 0 \). The kernel is spanned by \( A_{2r+1}^{0,1} \), that is, an element with this as its lowest order term. This, of course, is the equation
itself. Thus

$$E_{2p}^\infty = E_{2p}^{2q+1} = \begin{cases} A_{2p}^{0,0} & A_{2p}^{0,1} \\ m R \setminus m & R R 0 \\ m m & 0 0 1, \ldots, r - 1 \\ m R \setminus m & 0 R r \\ m 0 & 0 0 r + 1, \ldots, q - 1 \\ R \setminus m 0 & 0 0 q \\ R 0 & 0 0 q + 1, \ldots, 2q - r \\ 0 0 & 0 0 2q - r + 1, \ldots, 2q - 1 \\ R 0 & 0 0 2q \\ 0 0 0 0 2q + 1, \ldots \end{cases}$$

We see that

$$P_r^q[E_\infty^\cdot](t) = 2^{r-1} 2^{q-1} 2^{q-r} t^{2r} + \sum_{i=1}^{q-1} t^{2i} + \sum_{i=q+r+1}^{2q} t^{2i} + t^{4q}$$

and $I(E_\infty^\cdot) = 2q$. The codimension is $r+q-1$. This is the final result, since there is nothing useful to do for the $A_{2r}^{0,1}$ term in $E_{2r}^{2q+1}$. The $A_{0,0}^0$-term may be used to scale one of the coefficients in $R \setminus m$ to unity.

5.2.2. Case $A_\infty^\cdot$: no $\beta_{2,0}^0$ is invertible

The following analysis is equivalent to the one in [Bai89, Theorem 4.11], case (2), $k = r$.

Since we can eliminate all terms of type $A_{2p}^{0,1}$, and we find no terms of type $A_{2p}^{0,0}$ with invertible coefficients, we can draw the conclusion that the cohomology is spanned by the $A_{2p}^{0,0}$, but does not show up in the normal form.

$$E_{2p}^\infty = E_{2p}^{2r+1} = \begin{cases} A_{2p}^{0,0} & A_{2p}^{0,1} \\ m R \setminus m & R R 0 \\ m m & 0 R 1, \ldots, r - 1 \\ m R \setminus m & 0 R r \\ m 0 & 0 R r + 1, \ldots \end{cases}$$

We see that

$$P_r^\infty[E_\infty^\cdot](t) = \sum_{i=1}^{r} t^{2i}$$
and \( I(E^\infty) = r \). The codimension is infinite. Scaling the coefficient of \( A^0_1 \)
to unity uses up the action of \( A^0_0 \). Although we still have some freedom
in our choice of transformation, this freedom cannot effectively be used, so
it remains in the final result. We summarize the index results as follows.

The index of \( A^q_r \) is \( 2q \) if \( q \in \mathbb{N} \) and \( r \) otherwise.

### 5.3. The \( m \)-adic approach

So far we have done all computations modulo \( m \). One can now continue
doing the same thing, but now on the \( m \) level, and so on. The result will
be a finite sequence of \( m^p A^p_r \) describing exactly what remains. Here the
lower index can be either empty, a natural number or infinity and the upper
index can be a (bigger) natural number or infinity. The generating function
will be

\[
P[E^\infty](t) = \sum_p u^p P_{r_p}[E^\infty](t),
\]

with \( u^p \) standing for an element in \( m^p \setminus m^{p+1} \).

### APPENDIX A

The spectral sequence theorem

**Theorem A.1.** There exists on the graded module \( E^r \) a differential \( d_r \)
such that \( H(E^r) \) is canonically isomorphic to \( E^{r+1} \), \( r \geq 0 \).

**Proof.** We follow [God58] with modifications to allow for the converging boundary operators. The differential \( \partial_r \) maps \( Z^r_0 \) into \( Z^r_{p+r} \) and
\( \partial_r Z^{r-1}_{p-r+1} \) into \( \partial_r Z^{r-1}_{p+1} \). Let \( x \in \partial_r Z^{r-1}_{p+1} \). Then there is a \( y \in Z^{r-1}_{p+1} \) such that \( x = \partial_r y \in \partial_r Z^{r-1}_{p+1} \), using Property 3.1. Since

\[
E^r_{p+r} = Z^r_{p+r}/(\partial_r Z^{r-1}_{p+1} + Z^{r-1}_{p+1})
\]

one sees that \( \partial_r \) induces a map \( d^r_p : E^r_p \rightarrow E^r_{p+r} \). For \( x \in Z^r_p \)
to define a cocycle of degree \( p \) on \( E^r \) it is necessary and sufficient that \( \partial_r x \in \partial_r Z^{r-1}_{p+1} + Z^{r-1}_{p+r+1} \). (again using Property 3.1) \( \partial_r x = \partial_r y + z \) with
\( y \in Z^{r-1}_{p+1} \) and \( z \in Z^{r-1}_{p+r+1} \). Putting \( u = x - y \in Z^{r-1}_{p+1} \subset K_p \), with \( \partial_r u = \partial_r x - \partial_r y = z \in K_{p+r+1} \), one has \( u \in Z^{r+1}_{p+1} \), since \( \partial_{r+1} u - \partial_r u \in K_{p+r+1} \). In other words, \( x \in Z^{r-1}_{p+1} + Z^{r+1}_{p+r+1} \). It follows that the \( p \)-cocycles are given by

\[
Z^p(E^r) = (Z^{r+1}_{p+1} + Z^{r-1}_{p+1})/(\partial_{r-1} Z^{r-1}_{p-r+1} + Z^{r-1}_{p+1}).
\]
The space of $p$-coboundaries $B^p(E^r)$ consists of elements of $\partial_r Z^r_{p-r}$ and one has

$$B^p(E^r) = (\partial_r Z^r_{p-r} + Z^r_{p+1})/(\partial_{r-1} Z^r_{p-r+1} + Z^r_{p+1}). \quad (A.3)$$

It follows that

$$H^p(E^r) = (Z^r_{p+1} + Z^r_{p+1})/(\partial_r Z^r_{p-r} + Z^r_{p+1})$$
$$= Z^r_{p+1}/(Z^r_{p+1} \cap (\partial_r Z^r_{p-r} + Z^r_{p+1})). \quad (A.4)$$

We now first prove that $Z^r_{p+1} \cap Z^r_{p+1} = Z^r_{p+1}$. Let $x \in Z^r_{p+1} \cap Z^r_{p+1}$. Then $x \in K_{p+1}$ and $\partial_{r+1} x \in K_{p+1+r+1}$. Thus $\partial_r x \in K_{p+r+1}$ according to Property 3.1. This implies $x \in Z^r_{p+1}$. On the other hand, if $x \in Z^r_{p+1}$ we have $x \in K_{p+1} \subset K_p$ and $\partial_r x \in K_{p+r+1} \subset K_{p+r}$. Thus $x \in K_p$ and $\partial_r x \in K_{p+r+1}$. Again it follows that $\partial_{r+1} x \in K_{p+r+1}$, implying that $x \in Z^r_{p+1}$. Furthermore $x \in K_{p+1}$, $\partial_r x \in K_{p+r}$, implying that $\partial_{r-1} x \in K_{p+r}$ from which we conclude that $x \in Z^r_{p+1}$.

Now if $x \in \partial_r Z^r_{p-r}$, then $x = \partial_r y, y \in Z^r_{p-r}$, that is, $x \in Z^r_p$. Therefore $x \in K_p$, $\partial_{r+1} x = 0$, and it follows that $x \in Z^r_{p+1}$.

Since $Z^r_{p+1} \cap \partial_r Z^r_{p-r}, Z^r_{p+1} \cap Z^r_{p+1} = Z^r_{p+1}$, one has

$$H^p(E^r) = Z^r_{p+1}/(\partial_r Z^r_{p-r} + Z^r_{p+1}) = E^r_{p+1}. \quad (A.5)$$

In this way we translate normal form problems into cohomology.
